The TSC 6800 RELOCATOR is a very useful tool for any system owner, especially those who do assembly language programming. It can move blocks of information from one location in RAM to another. It can also relocate machine code programs from one place in RAM to another or from tape into RAM. Many variations are possible as you will see from using the RELOCATOR. The program is very easy to use as it prompts the user for all the information it needs. This manual explains the prompts and what they require in response. Included are 2 example relocations and the information necessary to relocate other TSC software. Also included is a co-resident link for the TSC TEXT EDITING SYSTEM and the TSC MNEMONIC ASSEMBLER.

First of all, here are some hints on how to respond to computer prompts. When asked a question by the computer, in general type a 'Y' for yes or an 'N' for no. When entering addresses, it is not necessary to type leading zeros. A return must be typed to terminate the address. Note that only the last 4 digits typed are accepted. Thus if you detect an error in typing before hitting a return, you can type a few zeros and then type the correct address.

WHAT THE PROMPTS MEAN:

- PRESENT PROGRAM; BEGIN ADDRESS? ... Hexadecimal address of the first byte to be relocated.
- PRESENT PROGRAM; END ADDRESS? ... Hexadecimal address of the last byte to be relocated.
- MOVE TO? ... Hexadecimal address of the location to which you are moving the present program.
- 4. FIX REFERENCES? ... Typing an 'N' will cause the program delimited in steps 1 and 2 above to be moved exactly as is, byte for byte, to the location specified in step 3 above. You will then exit the RELOCATOR. A 'Y' will allow the program to be relocated, fixing any extended addressing references that require a change. For a further description, read the section titled 'FIXING REFERENCES'.

- 5. LOAD FROM TAPE? ... Type an 'N' if the program you are relocating is in RAM. If you are relocating directly from tape, type a 'Y'. The program will go into a load mode, much as if you had typed an 'L' into a MIKBUG monitor. If there is an error during loading, you will be prompted 'LOAD ERROR! TRY AGAIN?'. Typing a 'Y' at this point will put you back into the load mode. An 'N' will cause an exit from the relocator program. If there are no load errors, upon receiving an 'S9' the computer will report, '... LOAD COMPLETED.' At this point the RELOCATOR will pause until you type a space.
- DATA BLOCKS? ... If the program you are relocating is made 6. of executable code only, type an 'N'. If there are blocks of data, print strings or etc., type a 'Y'. You will then be asked for 'BEGIN ADDRESS' and 'END ADDRESS' for as many blocks as you wish to enter. THESE BLOCKS MUST BE ENTERED IN ORDER. That is, the block with the lowest starting address must come first, the second lowest starting address comes next, and so To end the entering process, enter an 'FFFF' as the begin address of a block. For a more complete description of what is considered a 'data block,' see the section titled 'DATA BLOCKS'. NOTE: These addresses are placed on a stack beginning at the end of the RELOCATOR (\$06AD). Be sure you have enough RAM there for the number of blocks you enter!
- 7. ALTER RANGE? ... The 'range' is initially set to the beginning and the end of the program you are moving. This means that any JMP, JSR or other extended address instruction within that range will have an offset added to its reference (2nd and 3rd bytes) when relocated. Any extended instruction outside the range will be moved exactly as is, thus allowing monitor calls, external routine calls, etc. to be properly relocated. If you want the range left as is, type an 'N'. If you wish to change it, type a 'Y'. You will then be asked for the beginning and ending addresses of the new range.
- 8. FIX FDB'S? ... An FDB is a pseudo-op in standard 6800 assemblers. Its function is to define 2 bytes of RAM to be some specific value. If there are no FDB's in your program, type an 'N' and you are finished. If there are FDB's which are used to set up constants or data as opposed to addresses, they should not be changed, so type an 'N' in this case also. A common use for FDB's is to setup addresses for jump tables, command tables, etc. If your program has FDB's which setup addresses, but all those addresses are outside the range used for relocation, type an 'N' as they should not be altered. If the addresses are within the

range, you have two choices:

- (1) If the locations of the FDB's themselves are within range, type a 'Y'.
- (2) If the locations of the FDB's themselves are outside the range, type an '0' or any other character.

Now you will be asked for the address of the FDB itself. You may enter as many FDB's as you like and they need not be in any order. When finished, type an 'FFFF' as an address to stop the input mode.

RELOCATION COMPLETED!! . . . Self-explanatory!

LOADING FROM TAPE:

The TSC 6800 RELOCATOR has its own tape load routine which will read Motorola Mikbug format tapes. As each record is read, offset is added to the record's loading address if that address is within the range of the program. When the LOAD subroutine is called, the first thing it does is turn on the reader control bit of the Mikbug control PIA. Next a string of control characters is sent out. The string is called TAPEON (at location \$05AF) and is presently set to four nulls. If your tape system requires some special control characters, you may patch them into this string. DO NOT remove the '4' at the end, however. when the tape is completely loaded or when an error is received, the reader control bit of the Mikbug control PIA is turned off. Then a string called TAPOFF (at location \$05B4) is sent out. TAPOFF is currently set to four nulls, but you may replace them with any control characters your tape system requires. Again, DO NOT remove the '4' at the end of the string.

Note that the LOAD routine is written as a subroutine and may therefore be called from another program if desired. Before calling it, however, you must setup an appropriate OLDPTR (\$0213), OBJEND (\$0217), OFFSTL (\$021D), and OFFSTR (\$021E). These would generally be set to \$0000, \$FFFF, \$00 and \$00 for a normal load operation.

FIXING REFERENCES:

It is not usually possible to directly move a program from one location in memory to another due to the extended references (the full 2 byte addresses in 3 byte instructions). For example, if you have an instruction which says JUMP to \$1012, when the program is moved up by hex one hundred bytes it cannot stay the

same but must be changed to JUMP to \$1112. This is what is meant by 'fixing references.' The TSC 6800 RELOCATOR searches thru the instructions as they are moved and any extended references are singled out. These extended addresses are then compared to the range begin and end and if inside the range, the proper offset is added to the address. Any references to outside the range are left unchanged so that jumps to external routines, calls to monitor routines, etc. will be properly relocated.

DATA BLOCKS:

Almost every program has areas which contain some type of data as opposed to executable code. When relocating, we must know where these blocks are for if we did not, there would be no way of knowing what was data and what was instructions. The instructions must have their extended references (the 2nd and 3rd bytes of 3 byte instructions) adjusted. The data must be transferred as is, byte for byte. This is the reason for specifying DATA BLOCKS. All bytes within the begin and end addresses specified (inclusive) will be relocated exactly as they are.

How do you know what should be specified as a 'DATA BLOCK'? If you have a source listing, it is generally quite easy. Any code generated by an RMB, FCB, FCC or FDB should be considered data. That's usually all there is to it! Of course if you wanted, instructions could be placed in a DATA BLOCK which would cause them to be relocated as is without fixing their references. Sometimes you may need to directly move a 3 byte immediate instruction. See the section titled '3 BYTE IMMEDIATE INSTRUCTIONS' for further details.

If you don't have a source listing, finding the data blocks becomes more of a problem. One solution is to put the object code thru a disassembler and then search out all data. Study the example relocations included for more insight.

3 BYTE IMMEDIATE INSTRUCTIONS:

There is one type of instruction which can cause problems for a relocator. That being a 3 byte immediate instruction of which there are three in the 6800 microprocessor:

LOAD INDEX REGISTER IMMEDIATE (\$CE)
LOAD STACK POINTER IMMEDIATE (\$8E)
COMPARE INDEX REGISTER IMMEDIATE (\$8C)

In most cases the immediate bytes are an address. If that address is in range, it will be offset, otherwise it will be

directly relocated. This is the way it should be in almost all instances. You must keep an eye on the LDS command, however. Often one will say LDS immediate with an address outside the program, because you are setting up an external stack. Thus the stack will remain in the same place even though the program has been moved. If the stack is still out of the way, you have no problem, but it is something to look out for.

Another problem is in loading data into the index register or comparing the index register to data as opposed to an address. If the data is a number which is lower than the value of RANGE BEGIN or higher than the value of RANGE END, you have no problem. If, however, the data is a number inside the range, it will be altered as it looks like an address to the RELOCATOR. Although this does not occur often, it will give you an incorrect relocation.

To prevent these problems, you must know whether each occurence of a 3 byte immediate instruction contains immediate data or an immediate address. If it is an address, there will likely be no problem. If it is data, you should setup all 3 bytes of the instruction as a 'DATA BLOCK' as described above.

ADAPTING TO YOUR SYSTEM:

Adapting to your particular system is a very simple task. You must supply two routines. One is an output routine which outputs the A accumulator to your display and returns without affecting any other registers. The second is an input routine which inputs a character from your keyboard into the A accumulator and returns without affecting any other registers. You must patch the addresses of these routines into the RELOCATOR at \$8220 and \$0223. Upon completing a relocation, the program will jump to the address stored at MONITR (\$0226). You may patch any address you like here, such as the re-entry point of your monitor. If you are using a MIKBUG monitor, these 3 addresses are already set and need not be altered.

You may need to alter the location of the stack which is presently setup at \$0FFF. If this location is inconvenient for your particular system, you may change it by patching in the desired address at \$0201 in the RELOCATOR.

See the section titled 'LOADING FROM TAPE' for instructions on adapting to your particular tape system.

SAMPLE RELOCATIONS:

1) The TSC 6800 Relocator

This sample, will relocate the TSC 6800 RELOCATOR itself. The program starts at \$0200 and ends at \$06AF. Let's assume we want to move it to \$3200. Here is a copy of what the prompts and responses look like:

* TSC 6800 RELOCATOR *
PRESENT PROGRAM.
BEGIN ADDRESS? 200
END ADDRESS? 6AF
MOVE TO? 3200
FIX REFERENCES? Y
LOAD FROM TAPE? N
DATA BLOCKS? Y

BEGIN ADDRESS? 206 END ADDRESS? 21E

BEGIN ADDRESS? 581 END ADDRESS? 6AF

BEGIN ADDRESS? FFFF ALTER RANGE? N FIX FDB'S? N

RELOCATION COMPLETED !!!

Note that the stack remains at \$0FFF. It may be necessary to change its location. The stack is set immediately upon entering the program. Thus in the relocated version, it is set at \$3200. The instruction there is an LDS #. Change the \$0FFF there if necessary.

2) TSC Space Yoyage

SPACE VOYAGE actually begins at \$0000 and ends at \$0FFE. The first part is temporary storage in page 0, however, and cannot be moved. We will relocate only the program beginning at \$0100. Let's assume we want the program moved to \$1000. This relocation has an example of FDB's. They make up a jump table and thus are addresses. The FDB's themselves are outside the range, however, so an 'O' must be typed in response to the prompt, 'FIX FDB'S?' Here is what the relocation of SPACE VOYAGE looks like:

* TSC 6800 RELOCATOR *
PRESENT PROGRAM:
BEGIN ADDRESS? 100
END ADDRESS? FFE
MOVE TO? 1000
FIX REFERENCES? Y
LOAD FROM TAPE? N
DATA BLOCKS? Y

BEGIN ADDRESS? C55 END ADDRESS? FFE

BEGIN ADDRESS? FFFF ALTER RANGE? N FIX FDB'S? O ADDRESS? D5 ADDRESS? D7 ADDRESS? D8 ADDRESS? DB ADDRESS? DD ADDRESS? DF ADDRESS? E1 ADDRESS? E3 ADDRESS? E5 ADDRESS? E7 ADDRESS? FFFF

RELOCATION COMPLETED !!!

INFORMATION FOR RELOCATING OTHER TSC PRODUCTS:

1) Micro BASIC Plus

BEGIN ADDRESS: 100 END ADDRESS: D4F

THINGS TO CHECK:

- a) The end of memory is called MEMEND in the program and is setup at \$010F (before relocation). Change thus address to suit your system and new program location.
- b) Another thing to look out for is the external routine jump at \$0701. Change the 1F00 there to the address of your external routine. If you have no external routine, you must point this subroutine jump to an RTS command. For instance, you could change the 1F00 to the address of TSTLE2 (\$075E before relocation).

2) Stack Oriented Arithmetic Processor (SOAP)

BEGIN ADDRESS: 100 END ADDRESS: 640

MAKING THE ISC EDITOR AND ASSEMBLER CO-RESIDENT:

Following is a description of the steps necessary to relocate the TSC TEXT EDITING SYSTEM, allowing co-resident operation with the TSC 6800 MNEMONIC ASSEMBLER.

- 1) Load the RELOCATOR
- 2) Move it to \$3200 and set its stack pointer to \$3FFF (location \$3201 after relocation must be changed to \$3F)
- 3) Load the TSC TEXT EDITING SYSTEM
- 4) Load the program called 'LAS' which has been included with this documentation. Type in all code generated by that program.
- 5) Relocate the Editor-LAS pair according to the instructions given (Begin execution of the RELOCATOR at \$3200) below.
- 6> Load the TSC 6800 MNEMONIC ASSEMBLER
- 7) Begin execution at \$1700. See the LAS program for instructions on use and on adapting to a system larger than 16K.

RELOCATING THE EDITOR-LAS PAIR:

BEGIN ADDRESS: END ADDRESS: MOVE TO:	0200 1559 1700	ALTER RANGE? Y BEGIN ADDRESS: END ADDRESS:	01FF 1559
END ADDRESS: MOVE TO: DATA BLOCKS? Y BEG ADDR: 0214 END ADDR: 0354 [04458 [04458 [04464 [0476 [0476 [0476 [0955 [0988] [0988 [0988] [0
